1. Reflection

What was easy about this assignment was building out the rest of the classes. Having the bones of the class and practiced in previous weeks, I felt confident working with them. What was difficult for me was deciding on what collection I wanted to work with. At first, I considered using an array since it was present in the example, but I did not like that the arrays did not have a data relationship beyond sharing positions in their respective arrays. For example, the only reason that one equals January is that they are both at position zero. I ultimately went with a HashMap because the key-value pairs made sense to me: one is January, two is February, three is March, and so on. I can't say there is anything I wish I knew before the assignment. The only implementation decision I made that I feel has a rationale is using a HashMap instead of an array. This reasoning holds true with the array list. I would have needed multiple array lists that are correlated by position and have no actual data relationship. This is a personal preference, and I want the data to be related.
