1. Reflection

The most difficult part of the assignment was figuring out where to start. As I started writing the code, I realized that because of the relationships between classes, it would be wise to identify which classes depended on others and which did not. Writing the parking lot class before the address class was not a wise decision, as the parking lot class required an address. Using tools like Visio helped me create my class diagrams and show the relationships between classes. Saying I wish I had known this before isn't 100% accurate, but the lesson learned is to pay more attention to the instructions provided. I did not pay close attention to the instructions and did not realize that I needed to use the car class within the customer class. This forced me to go back and refactor my register method within my customer class to meet the requirement. It became clear to me that it made far more sense to use the classes and methods in that manner. Previously, I would have created a car and linked it to the user separately. This made the task seamless, allowing the car to be automatically linked to the customer who registered it. One implementation decision I made was for my testing. Many examples I've seen would call the class and create a new object with each test. I chose to create the new object at the beginning and call it for each test. The reason was to reduce redundant code and shorten my files.
