1. Discussion

Due to difficulties coordinating a time for the entire team to get together and work on this project as a group, I had to work on the assignment alone. As a result, I deliberated on the discussion question based on my own experience. When it comes to error handling and identifying and handling errors, I believe there is so much emphasis because, while as a developer you know how to use the code and the expected outcome, you cannot always guarantee that the end user will use it correctly. If a user throws in a piece of data that the code is not expecting, it may cause a complete software crash. Additionally, by managing inputs and ensuring misinputs are handled appropriately, you can mitigate the likelihood of exploitation of the software by those with more nefarious intentions. From my point of view, I believe that appropriate error handling almost always outweighs the cost; however, there is no way to account for everything, and trying to go down every rabbit hole, I feel, would lead to unnecessary costs in time and resources. At some point, I believe the code must be released and a continuous improvement effort established to address additional error handling throughout the software's life.
